27

years in medical data

4,000+

healthcare institutions served

40+

clinical AI agents deployed

Explore the capability

01 / RUNDA HEALTH

Medical data experience, translated into clinical AI.

Runda combines medical data governance, clinical knowledge and workflow engineering to build AI that can operate inside real hospital environments.

The platform is designed around traceability and clinician control. Outputs remain connected to their source data, governing knowledge and review history.

300+

AI and smart-hospital sites

10+ years

of medical data governance practice

1 foundation

supporting a growing portfolio of clinical agents

CLINICAL DATA X / CDX

01

Collect

Notes, labs, medications and reports from approved sources

02

Normalize

Terms, units, dates and local abbreviations become comparable facts

03

Connect

Facts link to longitudinal context, knowledge and governing rules

04

Serve

Agents receive controlled context and return a traceable result

ONE TRACEABLE EXAMPLE

Clinical note + lab result → normalized clinical fact → agent reasoning → clinician review

One governed patient context can support CDSA, documentation, quality, HeartEngine and the rest of Runda's clinical AI portfolio.

02 / REPRESENTATIVE PORTFOLIO

Seven selected agents from a portfolio of more than 40.

These examples show how governed clinical AI can support documentation, decision support and continuity of care without turning a portfolio into a fixed product catalogue.

BEFORE CARE

01

Before care / patient intake

AI Pre-Consultation

Collects symptoms, history, medications and allergies before the visit, then prepares a structured summary for clinician review.

02

Before care / screening

Breast Health

Supports risk assessment, screening guidance and continuity across follow-up care in a patient-friendly workflow.

DURING CARE

03

During care / clinical reasoning

CDSA

Turns longitudinal history, clinical knowledge and evidence into a traceable analysis for clinician review.

04

During care / documentation

Medical Record Generation

Uses encounter data to prepare an editable clinical draft. The clinician reviews, changes and signs the final record.

05

During care / documentation quality

Medical Record Quality

Checks completeness, consistency and quality requirements before the medical record is finalized.

06

During care / specialty intelligence

HeartEngine

Connects ECG, biomarkers, vital signs and history to a traceable cardiovascular risk analysis.

AFTER CARE

07

After care / continuous support

AI Health Assistant

Supports education, follow-up and symptom collection after discharge within a care pathway defined by the healthcare institution.

Extend governed support beyond discharge.

CLINICAL BOUNDARY

Different jobs. One accountability rule.

Each agent has a bounded role. The system can collect, structure, flag or draft; the clinician remains responsible for interpretation, change and sign-off.

01

Collect

AI Pre-Consultation organizes symptoms and history before the visit. It does not silently turn intake into a diagnosis.

02

Analyze

CDSA and HeartEngine return evidence-linked analysis, risks and options. The clinician decides what to accept or reject.

03

Draft & check

Record agents create an editable draft or a quality flag. The clinician reviews, edits and signs the final record.

04

Continue

AI Health Assistant follows an institution-defined pathway, with escalation and human review kept visible.

03 / DIGITAL FOUNDATION

Your clinical record remains the system of care.

Runda does not replace the systems healthcare teams rely on. It adds a governed clinical intelligence layer that works within approved data and workflow boundaries.

SYSTEM OF CARE

CLINICAL APPLICATION

ACCOUNTABILITY

Clinical record

Longitudinal patient data and established workflows

CONTROLLED ACCESS

Approved integration

FHIR, HL7, APIs, interface services or governed data views

INTELLIGENCE FOUNDATION

Runda CDx

Normalization, knowledge and traceability

Selected agent

A bounded task embedded in or returned to the care workflow

Clinician review

Return path, review and escalation defined with the institution

Potential data domains

Encounters and history

Medications and allergies

Vital signs

Diagnostic reports

Diagnoses and procedures

Laboratory results

Clinical notes

Orders and care plans

04 / FROM DEMONSTRATION TO OPERATION

Start with understanding. Add infrastructure only when the use case is clear.

01

Remote product demonstration

Pre-set sample cases show the workflow and interface. No patient data is connected, and no new AI server is required.

Understand the capability

02

Focused validation with de-identified cases

Select one agent, one clinical context and a small approved case set. Both sides agree measures before reviewing the output.

Test local usefulness

03

On-site POC or production deployment

After clinical value is accepted and scope is agreed, deploy a dedicated environment, connect approved systems, complete security review and operate with audit and support.

Run under institutional governance

There is no honest server answer before the workflow is chosen.

Infrastructure follows scope. Model, accelerator, concurrency, latency and data-flow requirements should be sized after the agent, users and operating context are known.

Application & data services

Run the governed product layer and approved clinical context.

AI compute

Size model, accelerator, concurrency and latency after the agent and users are known.

Network & security

Design data transfer, result return, HTTPS, access boundaries and failure handling together.

Operations

Includes monitoring, backup, release control and clinical acceptance from the beginning.

05 / BEYOND THE CATALOGUE

A clinical need does not have to fit an existing agent.

Runda can work with clinical and IT teams to design, validate and deploy institution-specific agents around real clinical priorities.

Every engagement starts with the care workflow, then identifies the approved data, clinical knowledge, integration and operating boundaries that make an agent useful and accountable.

01

Define the clinical need

Users, decisions and current workflow

02

Map the data context

Approved data, integration and access

03

Build the agent

Local terminology, knowledge and workflow logic

04

Validate clinically

Safety, usefulness and acceptance criteria

05

Deploy under governance

Controlled users, audit and measured operation

06 / AI SOVEREIGNTY

You control the AI built for your environment.

Runda provides the clinical AI foundation and agent-development capability. Each institution retains authority over its data, operating boundaries and institution-specific AI assets created for its environment.

01

Data

The institution determines which clinical data an agent can access and for what purpose.

02

Environment

Deployment, residency and access controls follow boundaries approved by the institution.

03

Governance

The institution defines users, permissions, review requirements and acceptable use.

04

Institution-specific assets

Institution-specific agents, workflow configurations and local knowledge assets remain governed by the institution.

Ownership and usage rights for institution-specific assets are reflected in final commercial and IP terms. Runda's pre-existing platform technologies remain Runda intellectual property.

01

Define the clinical need

Users, decisions and current workflow

02

Map the data context

Approved data, integration and access

03

Build the agent

Local terminology, knowledge and workflow logic

04

Validate clinically

Safety, usefulness and acceptance criteria

05

Deploy under governance

Controlled users, audit and measured operation

07 / SELECTED EVIDENCE

Operating experience across scale, specialty depth and localization.

Four deployments show different dimensions of Runda's clinical AI experience. Each result belongs to its specific implementation context.

IMSS

LOCALIZATION AT NETWORK SCALE

Mexico / IMSS

78M

people served

1,700+

facilities
